We watch TV on computers, phones, and other mobile devices; television is now online as much as it is "on air." Television and New Media introduces readers to the ways that new media technologies have transformed contemporary broadcast television production, scheduling, distribution, and reception practices. Drawing upon recent examples including *Lost*, *24*, and *Heroes*, this book examines the ways that television programming has changed—transforming nearly every TV series into a franchise, whose on-air, online, and on-mobile elements are created simultaneously and held together through a combination of transmedia marketing and storytelling. Television studios strive to keep their audiences in constant interaction with elements of the

show franchise in between airings not only to boost ratings, but also to move viewers through the different divisions of a media conglomerate. Organized around key industrial terms—platforming, networking, tracking, timeshifting, placeshifting, schedule-shifting, micro-segmenting, and channel branding this book is essential for understanding how creative and industrial forces have worked together to transform the way we watch TV.

A cellular network or mobile network is a wireless network distributed over land areas called cells, each served by at least one fixed-location transceiver, known as a cell site or base station. In a cellular network, each cell uses a different set of frequencies from neighboring cells, to avoid interference and provide guaranteed bandwidth within each cell. When joined together these cells provide radio coverage over a wide geographic area. This enables a large number of portable transceivers (e.g., mobile phones, pagers, etc.) to communicate with each other and with fixed transceivers and telephones anywhere in the network, via base stations, even if some of the transceivers are moving through more than one

cell during transmission. Cellular networks offer a number of desirable features: More capacity than a single large transmitter, since the same frequency can be used for multiple links as long as they are in different cells Mobile devices use less power than with a single transmitter or satellite since the cell towers are closer Larger coverage area than a single terrestrial transmitter, since additional cell towers can be added indefinitely and are not limited by the horizon Major telecommunications providers have deployed voice and data cellular networks over most of the inhabited land area of the Earth. This allows mobile phones and mobile computing devices to be connected to the public switched telephone network and public Internet. Private cellular networks can be used for research or for large organizations and fleets, such as dispatch for local public safety agencies or a taxicab company.

On the data link layer local area networks (LANs) are introduced together with the most popular LAN technologies such as Ethernet, Token Ring, FDDI, and ATM as well as wireless LAN technologies including IEEE 802.x, Bluetooth, or ZigBee. A wide range of WAN technologies are covered including contemporary high speed technologies like PDH and SDH up to high speed wireless WANs (WiMAX) and 4th generation wireless telephone networks LTE. Routing technologies conclude the treatment of the data link layer. Next, there is the Internet layer with the Internet protocol IP that establishes a virtual uniform network out of the net of heterogeneous networks. In detail, both versions, IPv4 as well as the successor IPv6 are covered in detail as well as ICMP, NDP, and Mobile IP. In the subsequent
